DATABASE MANAGEMENT SYSTEM

ASSIGNMENT-4

UE19CS301

Team - 24

Divyanshu Sharma: PES1UG20CS806

Navya C: PES1UG20CS818

Dependencies installed for the database connectivity:

The front-end of our database was implemented using PHP, which is a popular front-end framework which uses CSS and JavaScript-based design templates.

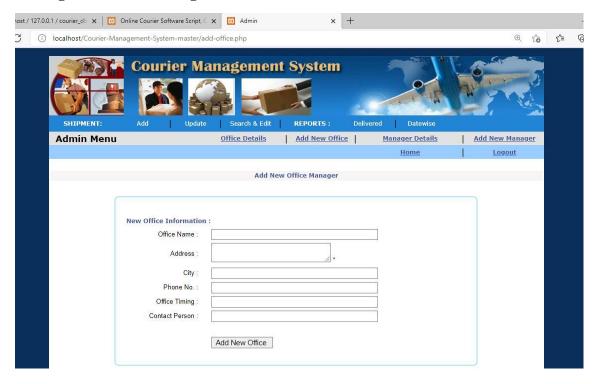

We utilized MYSQL to structure our database and the required dependencies used to connect the front-end to the back-end was phpMyAdmin, which is a free and open-source administration tool used for MYSQL.

Execution on the frontend with sample queries:

Viewing all Manager Details:

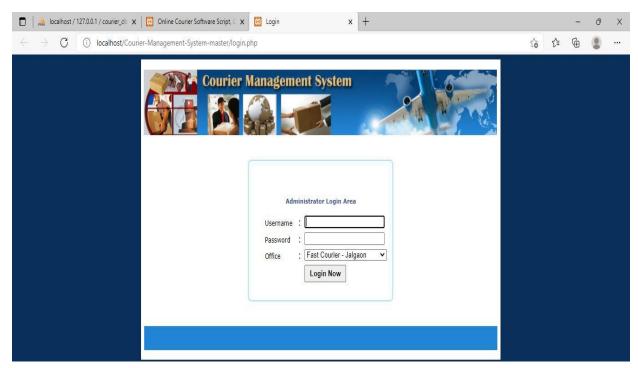

Adding New Office Manager Details:

Home Page:

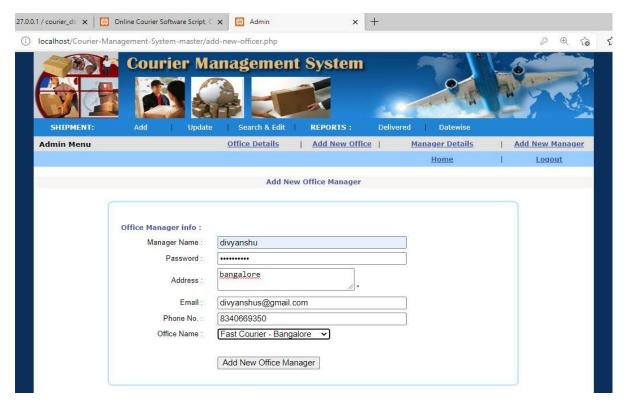

Administrator Login Page:

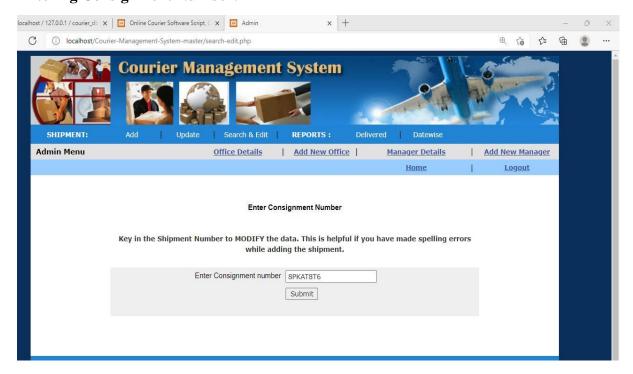

Viewing all Office Details:

Adding New Office Manager Details:

Entering Consignment Number:

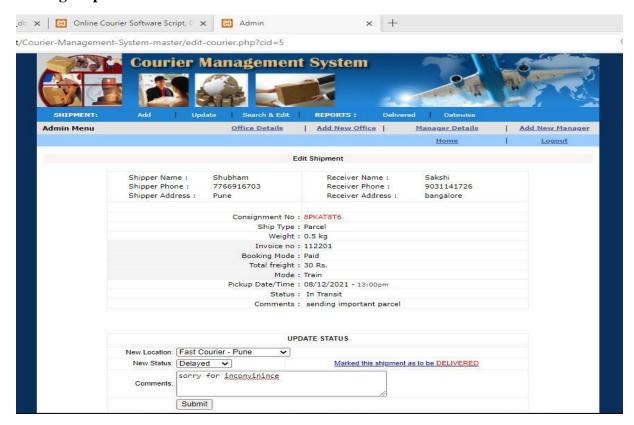

Updating Shipment Details:

Editing Shipment Details:

Tracking and Tracing the Courier:

Schema & Constraint Change Statement

 For the 'couriers' entity: Source, Destination and dest_ph attributes were added.

ALTER TABLE couriers ADD Source varchar(50);

```
=# ALTER TABLE couriers ADD Source varchar(50);
ALTER TABLE
courier=# \c couriers;
FATAL: database "couriers" does not exist
Previous connection kept
ourier=# \d couriers;
                           Table "public.couriers"
Type | Collation | Nullable | Default
   Column |
               | integer
cour id
                                                             not null
shipment_id
office_id
                  integer
                                                             not null
                character varying(40)
               character varying(50)
character varying(12)
character varying(50)
 destination
dest ph
ndexes:
    "couriers_pkey" PRIMARY KEY, btree (cour_id, courier_name)
```

ALTER TABLE couriers ADD Destination varchar(50);

```
courier=# ALTER TABLE couriers ADD destination varchar(50);
ALTER TABLE
courier=# \d couriers;
                         Table "public.couriers"
                                 | Collation | Nullable | Default
    Column
                         Type
cour_id
              integer
                                                       not null
shipment_id | integer
office_id | integer
                                                       not null

courier_name | character varying(40)
                                                      not null
              character varying(12) character varying(50)
dest_ph
source
destination | character varying(50)
Indexes:
    "couriers_pkey" PRIMARY KEY, btree (cour_id, courier_name)
```

ALTER TABLE couriers ADD dest_ph varchar(12);

```
ourier=# ALTER TABLE couriers ADD dest_ph varchar(50);
ALTER TABLE
courier=# \d couriers;
                          Table "public.couriers"
   Column
                                        | Collation | Nullable | Default
cour_id
               integer
                                                         not null
shipment_id | integer office_id | integer
                                                         not null
                                                         not null
courier_name | character varying(40)
                                                         not null
source | character varying(50) destination | character varying(50)
dest_ph
            character varying(50)
Indexes:
    "couriers_pkey" PRIMARY KEY, btree (cour_id, courier_name)
```

• For the 'customer' entity: password attribute was added

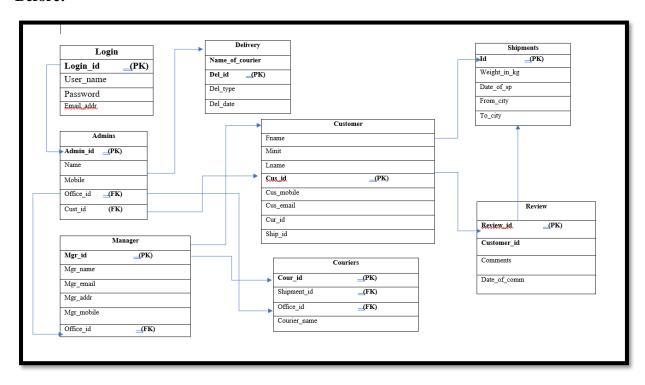

ALTER TABLE customer ADD password varchar(255);

```
courier=# ALTER TABLE customer ADD password varchar(50);
ALTER TABLE
courier=# \d customer;
                  Table "public.customer"
                  Type | Collation | Nullable | Default
  Column
cus_id | integer
                                          not null
not null
                                         not null
                                         not null
                                         not null
                                         not null
Indexes:
   "customer_pkey" PRIMARY KEY, btree (cus_id)
```

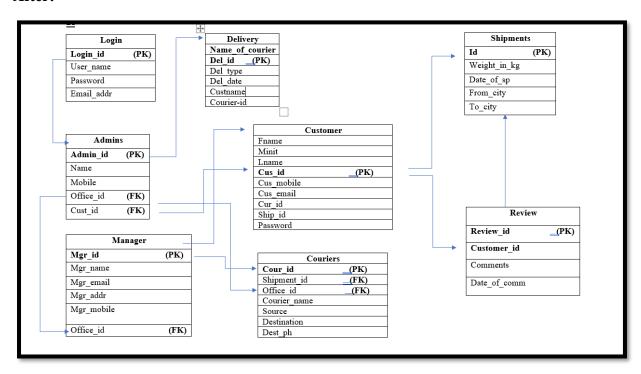

• For the 'delivery' entity: **custname** and **courier_id(foreign key)** attributes were added

ALTER TABLE delivery ADD custname varchar(25);

Before:

After:

Changes in Business/Application:

Changes in the Application or expansion is to make working software available at cloud, so that customers can access and process it at all time.

With the existing design of your database, if you have to migrate to any No-SQL variety, which one will be your choice? Why?

If we have to migrate to a No-SQL variety then our preferred choice would be a document database. These databases store data in CSV,JSON, BSON, or XML formats. These documents can be retrieved and stored in a similar format as that of data objects used in applications which implies minimal requirement for translations. Document databases are known to be very flexible i.e. structuring and reworking the databases are per need, which not only makes it time efficient but also allows its developers to have full control over it.

Migration from Mysql to Postgresql:

Link: enterprisedb.com/postgres-t-export-data-using-csv-files-postgresql

The most commonly used document database is POSTGRE SQL.

Following are a few key differences between MySQL and POSTGRE SQL:

- MySQL is a Relational Database Management System (RDBMS) and PostgreSQL is an object-relational Database Management System (ORDBMS). In Relational Database Models, the database is represented as a collection of relations. An ORDBMS has qualities of an RDBMS and in addition to that, it has several features of object-oriented management systems like objects, classes, and inheritance.
- PostgreSQL is ACID (Atomicity Consistency Isolation Durability) compliant while MySQL is not ACID-compliant. MySQL is ACID-compliant only with Inno DB (an ACID-compliant storage engine for MySQL) and NDB (Network Database) cluster engines.
- PostgreSQL has Multi-Version Concurrency Control (MVCC) which enables multiple users to work on a PostgreSQL database simultaneously. MySQL provides MVCC support only after using Inno DB.
- MySQL provides MySQL Workbench as a GUI tool, PostgreSQL provides PgAdmin.
- MySQL only supports standard data types (string, numeric, date, and time) while PostgreSQL supports advanced data types such as arrays, hstore, and user-defined data types.
